

Figure 1

1
 2 **Figure 1. PICALM siRNA knockdown alters cholesterol trafficking to the inclusion.**
 3 HeLa cells seeded in a 24-well plate were transfected with 20 nM of PICALM or non-
 4 targeting (NT) siRNA as described in Methods and Materials and then infected with *C.*
 5 *trachomatis* serovar L2 using an MOI of 0.5. (A) To confirm PICALM knockdown, cell
 6 lysates were harvested and resolved via SDS-12%PAGE and western blot to detect
 7 PICALM and GAPDH (loading control). These data are representative of knockdown of
 8 PICALM with siRNA obtained for all experiments with only samples demonstrating a
 9 70% or greater knockdown efficiency being used for data production. (B and C) After
 10 fixation, HeLa cells were incubated with filipin as described in Methods and Materials.

11 Images in C were captured with a Zeiss Axio Imager without the ApoTome at 100x
12 magnification, scale bar = 10 μ m. The same exposure time was used for all imaging. To
13 quantify the intensity of filipin, as a marker for cholesterol, an inclusion membrane
14 marker (inclusion membrane protein IncA) was used to determine regions of interest
15 (ROIs) in Fiji/ImageJ, which was also used to determine the integrated density of filipin
16 and the area of the inclusions within the ROIs. 60 inclusions total (30 in 2 independent
17 experiments) were measured. For each ROI the integrated density was divided by the
18 area of the inclusion, then individual data points, mean, and standard error of the mean
19 graphed in GraphPad Prism. Statistical significance was determined using an unpaired t
20 test. Data are representative of 4 independent experiments.

21

22

23 **Figure 2. PICALM siRNA knockdown prevents Golgi mini-stack formation around**

24 **the inclusion.** (A) HeLa cells depleted of PICALM or not (NT) with siRNA were infected

25 with *C. trachomatis* serovar L2 for 24 hours. Cells were fixed and processed for indirect

26 immunofluorescence to detect the Golgi (red; giantin) and the inclusion membrane

27 (blue, IncA). Images were taken on a Zeiss Axio Imager with ApoTome at 100x. Scale

28 bar = 10 μ m. (B) Examples of a fully fragmented Golgi, a partially fragmented Golgi, and
29 a Golgi with no fragmentation to manually determine (C) the percentage of Golgi
30 fragmentation in PICALM or NT siRNA transfected cells. Golgi fragmentation
31 phenotypes were graphed as parts of a whole in GraphPad Prism. (D and E). At 18-20
32 hours post infection, cells were labeled with NBD-ceramide, followed by a minimum of 3
33 hours of back-exchange to remove all non-incorporated fluorescent lipid from the cell
34 (essentially as described in PMID 23798538). Labeled cells were imaged live in the
35 brightfield and 488 fluorescent channels (set at the same exposure time for all samples)
36 on the Zeiss Axio Imager without the ApoTome at 40x; scale bar = 20 μ m. To measure
37 the intensity of NBD-lipid remaining within the inclusions, inclusions were identified and
38 marked as ROIs in Fiji/ImageJ in the brightfield image. Then, in the 488 channel
39 images, the integrated density and area of the inclusions were determined. Individual
40 integrated density values were divided by the associated area of the inclusion for 50
41 inclusions per siRNA knockdown condition. Individual values with mean and standard
42 deviation were graphed and statistically analyzed (Welch's t test) in GraphPad Prism
43 (D). Representative images are provided in E. These data are representative of 4
44 independent experiments.

A. Colocalization of Filipin and Giantin

B. Colocalization of Filipin and VAMP3

Figure 3

45
 46 **Figure 3. PICALM siRNA knockdown increases colocalization of cholesterol in the**
 47 **Golgi and within VAMP3-positive structures.** HeLa cells were transfected and
 48 infected with *C. trachomatis* serovar L2 as previously described. At 24 hours post-
 49 infection, cells were fixed and labeled with filipin prior to incubation with antibodies to
 50 detect the Golgi (giantin) (A) or VAMP3 (B). The Pearson's coefficients of 40
 51 cells/regions of interest were determined with the JACoP plugin in Fiji/ImageJ as
 52 described in Methods and Materials. For A and B, data are combined from 2
 53 independent experiments (consistent exposure times for each set of slides) and are
 54 representative of 4 independent experiments. In GraphPad Prism, individual data points

55 are graphed with mean and standard error of the mean. Statistical analysis included
56 ordinary One-way Anova with a Šidák's multiple comparison test. (C). Trafficking of
57 VAMP3 to the inclusion in NT or PICALM siRNA-transfected cells was determined after
58 fixation at 24 hours post-infection. Cells were processed for indirect
59 immunofluorescence to detect VAMP3 (green), IncA (inclusion membrane, red), or DNA
60 stained with DAPI. Images were captured with a Zeiss Axio Imager without the
61 ApoTome at 100x magnification, scale bar = 10 μ m. The same exposure time was used
62 for all imaging. White stars denote the chlamydial inclusions. Regions of interest were
63 generated in ImageJ using IncA as a marker for the inclusion and the integrated density
64 of VAMP3 around the inclusions was measured and divided by the area. The mean with
65 standard deviation was graphed in GraphPad Prism. Statistical significance was
66 determined with an unpaired t test where ns = not significant and **** $p \leq 0.0001$. These
67 data are representative of at least 3 independent experiments.

68

A. Colocalization of Filipin and HTR **B. Colocalization of Filipin and Rab11**

Figure 4

69

70 **Figure 4. PICALM siRNA knockdown and chlamydial infection increases the**
71 **colocalization of cholesterol (filipin) with Human Transferrin Receptor (HTR) and**
72 **Rab11 positive structures.** Images from experiments described Supplemental Figure
73 2 were used to determine the colocalization of cholesterol (labeled with filipin) with
74 HTR(A) or Rab11 (B). Briefly, individual cells within original 8-bit images were selected
75 as regions of interest (ROI) and exported using the multi-crop function of the ROI
76 manager in Fiji/ImageJ for the channel associated with filipin and Rab11 or HTR. The
77 Pearson's coefficient was determined using the JACoP plugin in Fiji for 40 cells/regions
78 of interest. Data are combined from 2 independent experiments (consistent exposure
79 times for each set of slides) and are representative of 4 independent experiments. In

80 GraphPad Prism, individual data points are graphed with mean and standard error of
81 the mean. Statistical analysis included ordinary One-way Anova with a Šidák's multiple
82 comparison test.

83

Figure 5

84

85 **Figure 5. Transferrin trafficking is altered in PICALM deficient cells.** HeLa cells
86 seeded in a 24-well plate were transfected with 20 nM of PICALM or non-targeting (NT)
87 siRNA as described in Methods and Materials and then infected with *C. trachomatis*
88 serovar L2 using an MOI of 0.5. (A and B) Infected cells were fed with 25 µg/mL
89 Transferrin-488 (green; Life Technologies) at 24 hours post infection and incubated for
90 an additional hour at 37°C 5% CO₂ to allow for transferrin internalization and trafficking.
91 Cells were fixed and processed for indirect immunofluorescence to detect Human
92 Transferrin Receptor (HTR) (A; red) or Rab11 (B; red) and the inclusion membrane
93 (IncA, blue). Images were acquired with the same exposure time on a Zeiss Axio

94 Imager without ApoTome at 100x magnification, scale bar = 10 μ m. In Fiji/ImageJ,
95 regions of interest were generated using IncA as a marker for the inclusion membrane
96 and the the area of the inclusion and the integrated density of HTR (A), Rab11 (B), or
97 transferrin-488 (C) was measured. Integrated density was divided by the area of the
98 inclusion with the mean and standard deviation graphed in GraphPad Prism. Statistical
99 significance was determined with an unpaired t test, **** $p \leq 0.0001$. These data are
100 representative of at least 3 independent experiments.

101

Figure 6

103 **Figure 6. Endogenous Rab11-FIP1 accumulates around *C. trachomatis* L2**
104 **inclusions throughout the developmental cycle.** HeLa cells seeded in a 24-well plate
105 were infected with *C. trachomatis* serovar L2. At indicated timepoints post-infection cells
106 were fixed and processed for indirect immunofluorescence to detect endogenous
107 Rab11-FIP1 (red), chlamydial organisms (green), and DNA in blue (DAPI Life
108 Technologies). Images were taken at 100x on a Zeiss Axio Imager with ApoTome, scale
109 bar = 10 μ m. These images are representative of at least 3 independent experiments.
110

Figure 7

111

112

113

114

Figure 7. Effect of PICALM siRNA knockdown on Rab11-FIP1 trafficking. HeLa cells were transfected, infected for 24 hours, fixed, and labeled with filipin as described previously. Images were acquired with the Zeiss Axio Imager without the ApoTome at

115 100x magnification, scale bar = 10 μ m. Images in A are representative of 4 independent
116 experiments with filipin (blue), Rab11-FIP1 (green), inclusion membrane (red, IncA),
117 organisms and DNA (purple). White stars indicate chlamydial inclusions. For data in B,
118 the original 8-bit images generated with the Zeiss software were used. Individual cells
119 were selected as regions of interest (ROI) and exported with the multi-crop function of
120 the ROI manager in Fiji/ImageJ for the channel associated with filipin or Rab11-FIP1.
121 The Pearson's coefficient was determined using the JACoP plugin in Fiji for 40
122 cells/regions of interest. These same images were used to determine the intensity of
123 Rab11-FIP1 at the inclusion in cells transfected with NT or PICALM siRNA (C). For
124 these data, the inclusions, as demarcated with an inclusion membrane marker IncA,
125 were identified as regions of interest in Fiji/ImageJ. Then the intensity of Rab11-FIP1 at
126 the inclusion was determined in the green channel. Data are combined from 2
127 independent experiments (consistent exposure times for each set of slides) and are
128 representative of 4 independent experiments. In GraphPad Prism, individual data points
129 are graphed with mean and standard error of the mean. Statistical analysis included
130 ordinary One-way Anova with a Šidák's multiple comparison test (B), and a Welch's t
131 test (C).

132

Supplemental Figure 1

133

134 **Supplemental Figure 1. BODIPY-cholesterol remains within the Golgi.** TopFluor

135 Cholesterol (aka BODIPY-cholesterol; Avanti Polar Lipids, Alabaster Alabama) was

136 resuspended in 2mg/100 λ . Then, 20 λ of the solution was added to serum-free DMEM

137 containing 10% methyl- β cyclodextrin (M β CD). A 400 μ g/ml stock of M β CD-TopFluor

138 Cholesterol complexes were made by 2 minutes of sonication. To remove large

139 particles, the complexes were then centrifuged for 2 minutes at 17,000 x g. Then 25

140 μ g/ml M β CD-TopFluor Cholesterol complexes were added to each well and incubated

141 for 4 hours, then cells were imaged live using the DIC and 488 fluorescent channels on

142 the Zeiss Axio Imager without the ApoTome at 40x magnification. These are

143 representative images from 4 independent experiments. Example inclusions and Golgi
144 are indicated in each image.

	NT siRNA	PICALM siRNA
Mean	0.2696	0.2748
Std. Deviation	0.1190	0.1001
Std. Error of Mean	0.01190	0.01001

Supplemental Figure 2

145

146 **Supplemental Figure 2. PICALM siRNA knockdown does not affect the size of the**
147 **Golgi.** Area of the Golgi was determined by selecting Golgi, using giantin as a
148 subcellular marker for the Golgi, in Fiji/ImageJ using the region of interest tool. The area
149 for 100 Golgi in HeLa cells transfected with NT or PICALM siRNA were determined in
150 Fiji and graphed and statistically analyzed with a Welch's t test in GraphPad Prism.

151

B. Colocalization of Rab11 and Human Transferrin Receptor

Supplemental Figure 3

152

153 Supplemental Figure 3. Cholesterol trafficking in PICALM siRNA treated cells.

154 HeLa cells were transfected with non-targeting (NT) or PICALM siRNA as described in

155 Methods and Materials, then infected with *C. trachomatis* serovar L2 (moi 0.7) for 24

156 hours. Cells were fixed in 4% paraformaldehyde and labeled with 50 μ g/ml filipin in

157 DPBS + 1% BSA for 1 hour at room temperature. Then samples were incubated with

158 the appropriate primary and secondary antibodies to detect Rab11 (green) and Human

159 Transferrin Receptor (red). Images were acquired with the Zeiss Axio Imager without

160 the ApoTome at 100x magnification, scale bar = 10 μ m. Images in A are representative
161 of 4 independent experiments and correspond with data in Figure 4. For data in B, the
162 original 8-bit images generated with the Zeiss software were used. Individual cells were
163 selected as regions of interest (ROI) and exported with the multi-crop function of the
164 ROI manager in Fiji/ImageJ for the channel associated with Rab11 or Human
165 Transferrin Receptor. The Pearson's coefficient was determined using the JACoP plugin
166 in Fiji for 40 cells/regions of interest. Data are combined from 2 independent
167 experiments (consistent exposure times for each set of slides) and are representative of
168 4 independent experiments. In GraphPad Prism, individual data points are graphed with
169 mean and standard error of the mean. Statistical analysis included ordinary One-way
170 Anova with a Šidák's multiple comparison test.

171

172

173

174

Supplemental Figure 4

175

176 **Supplemental Figure 4. Effect of PICALM knockdown on the generation of**

177 **chlamydial infectious progeny.** (A) HeLa cells depleted of PICALM or not using

178 siRNA were infected with *C. trachomatis* serovar L2 for 24 hours. Cells were fixed and

179 processed for indirect immunofluorescence to detect the inclusion membrane in green

180 (sheep anti-IncA Seramun Diagnostica GmbH), chlamydial organisms in red (Guinea

181 pig anti-L2 Rocky Mountain Labs), and DNA in blue (DAPI Life Technologies). Images

182 were acquired at 100x using a Zeiss Axio Imager with ApoTome. Scale bar = 10 μ m. (B)

183 Inclusion forming units (IFU) per mL were determined by collecting a primary infection in

184 either PICALM or NT siRNA knockdown cells at 24 and 48 hpi. Bacteria were re-
185 infected onto fresh monolayers of untransfected HeLa cells and IFU/mL were
186 enumerated as described in materials and methods. The mean with standard deviation
187 was graphed in GraphPad Prism.
188

189 Supplemental Figure 5

190

191 **Supplemental Figure 5. siRNA knockdown of PICALM increases VAMP4**

192 **trafficking to the inclusion.** HeLa cells seeded in 24-well plates were transfected with
193 either PICALM or NT siRNA for 18 hours. Media was removed and replaced, and cells
194 were allowed to recover for 24 hours. Then cells were infected with *C. trachomatis*
195 serovar L2. At 24hpi cells were fixed and processed for indirect immunofluorescence to
196 detect VAMP4 in green (rabbit anti-VAMP4 Sigma) and IncA in red (sheep anti-IncA
197 Seramun Diagnostica GmbH), and DNA in blue (DAPI Life Technologies). Images were
198 acquired on a Zeiss Axio Imager with ApoTome at 100x, scale bar = 10 μ m. White stars
199 denote chlamydial inclusions. VAMP4 inclusion intensity was determined by acquiring
200 images at the same exposure time without the ApoTome at 100x. Regions of interest
201 were generated in ImageJ using IncA as a marker for the inclusion and the integrated
202 density of VAMP4 around the inclusions was measured and divided by the area. The
203 mean with standard deviation was graphed in GraphPad Prism. Statistical significance
204 was determined with an unpaired t test where ns = not significant and **** $p \leq 0.0001$.
